Chi-square test

Terminology

Goodness of fit

Example of the Chi-square test

Performing the Chi-square test in spreadsheets

Pros and Cons

Usecases

Conclusion

Chi-square Test(χ^2 test)

-
- Chi-square test is a non-parametric test (a non-parametric statistical test is a test whose model does not specify conditions about the parameter of the population from which the sample is drawn.).
 - It is used for identifying the relationship between a categorical variable and denoted by χ^2 .
 - 1900 **Karl Pearson** developed published a paper on the χ^2 test

Chi-square Test(χ^2 test)

$$\chi^2 = \sum \frac{(O - E)^2}{E}$$

- It is a statistical test that can be used to determine what observed frequencies are significantly different from expected frequencies or not in one or more categories.
- In the mathematical expression, it is the ratio of experimentally observed result/frequencies (O) and the theoretically expected results (E) based on certain hypotheses, or it is calculated by dividing the overall deviation from the observed and expected frequencies by the expected frequencies.

Chi-square Test(χ^2 test)

If there is no difference in observed and expected frequencies, then the chi-square value would be zero.

If there is a difference, then the value of chi-square would be more than zero.

Chi-square Test(χ^2 test)

Three types of chi-square tests:

Goodness of fit

Test of independence

Test of homogeneity

Chi-square probability distribution graph

Terminology

- **Contingency table:** This is a cross table or two-way table.
- Its used to show the one variable in a row and another in a column with their frequency count.
- It is a type of frequency distribution table of the **categorical variables**.

Terminology

- **Observed frequencies:** Are counts made from experimental data. In other words, you observe the data happening and take measurements.
- **Expected frequencies:** Are counts calculated using probability theory. Expected frequencies are calculated for each cell in the contingency table.

Terminology

- **Observed frequencies:** Are counts made from experimental data. In other words, you observe the data happening and take measurements.
- **Expected frequencies:** Are counts calculated using probability theory. Expected frequencies are calculated for each cell in the contingency table.

$$E_{ij} = \frac{T_i * T_j}{N}$$

Where,

- E_{ij} : Expected frequency for i th row and j th column
 - T_i : Total in the i th row
 - T_j : Total in the j th row
 - N : Grand Total
- (row total * column total) / grand total

Terminology

Null Hypothesis (H₀):

- It states that no association exists between the two cross-tabulated variables in the population.
- Hence, the variables are statistically independent.
- For example, if you compare two methods A and B for its goodness or which one works better, and if the assumption is that both methods are equally good, then this assumption is known as the **Null Hypothesis**.

Terminology

Alternate Hypothesis (HA):

- It proposes that the two variables are related to the population.
- If you assume that from two methods, method A is superior to method B or method B is superior to method A, then this assumption is known as **Alternative Hypothesis**.

Terminology

Degree of Freedom: The number of independent variates that make up the statistic is known as the degree of freedom of that statistic.

$$DOF = (r - 1) * (c - 1)$$

Where,

- r=numbers of rows
- c=number of columns

This will be used in the test of independence and test of homogeneity, not in the goodness of fit.

Terminology

- **Chi-square test Statistics:** A chi-squared statistic is a single number that tells you how much difference exists on your observed counts and the counts you would expect if there were no relationship at all in the population.
- **Chi-Square p-value:** Chi-square P-value will tell you if your test results are significant or not.

Types of Chi-square test

Goodness of fit:

- Chi-Square goodness of fit test is a non-parametric test that is used to find out how the observed value of a given phenomenon is significantly different from the expected value.
- In this test, you only have one variable from a single population
- **Null hypothesis (H_0):** In the Chi-Square goodness of fit test, the null hypothesis assumes that there is no significant difference between the observed and the expected value ([Source](#)).
- **Alternative hypothesis (H_a):** In the Chi-Square goodness of fit test, the alternative hypothesis assumes that there is a significant difference between the observed and the expected value ([Source](#)).

Types of Chi-square test

Goodness of fit:

- **Null hypothesis (H_0):** In the Chi-Square goodness of fit test, the null hypothesis assumes that there is no significant difference between the observed and the expected value ([Source](#)).
- **Alternative hypothesis (H_a):** In the Chi-Square goodness of fit test, the alternative hypothesis assumes that there is a significant difference between the observed and the expected value ([Source](#)).

Types of Chi-square test

Goodness of fit:

- A student rolled a fair 6-sided die 60 times and got the observed frequencies.

| Die Value | Assumed Distribution | Observed Frequency |
|-----------|----------------------|--------------------|
| 1 | $1/6$ | 9 |
| 2 | $1/6$ | 15 |
| 3 | $1/6$ | 9 |
| 4 | $1/6$ | 8 |
| 5 | $1/6$ | 6 |
| 6 | $1/6$ | 13 |
| | | |

Types of Chi-square test

Goodness of fit:

- A student rolled a fair 6-sided die 60 times and got the observed frequencies.
 - H_0 The die is fair
 - H_a The die is not fair

Types of Chi-square test

Goodness of fit:

- A student rolled a fair 6-sided die 60 times and got the observed frequencies.

| Die Value | Assumed Distribution | Observed Frequency | expected | o-e | $(o-e)^2/e$ |
|-----------|----------------------|--------------------|----------|-----|-------------|
| 1 | 1/6 | 9 | 10 | -1 | 0.1 |
| 2 | 1/6 | 15 | 10 | 5 | 2.5 |
| 3 | 1/6 | 9 | 10 | -1 | 0.1 |
| 4 | 1/6 | 8 | 10 | -2 | 0.4 |
| 5 | 1/6 | 6 | 10 | -4 | 1.6 |
| 6 | 1/6 | 13 | 10 | 3 | 0.9 |
| | | 60 | | | 5.6 |

Chi-Square Distribution sheet

Critical Values of Chi-Square Distributions

| df | x^2 Right-Tail Area | | | | | | | | | |

Types of Chi-square test

Goodness of fit:

- A student rolled a fair 6-sided die 60 times and got the observed frequencies.

| Die Value | Assumed Distribution | Observed Frequency | expected | o-e | (o-e) ² /e |
|-----------|----------------------|--------------------|----------|-----|-----------------------|
| 1 | 1/6 | 9 | 10 | -1 | 0.1 |
| 2 | 1/6 | 15 | 10 | 5 | 2.5 |
| 3 | 1/6 | 9 | 10 | -1 | 0.1 |
| 4 | 1/6 | 8 | 10 | -2 | 0.4 |
| 5 | 1/6 | 6 | 10 | -4 | 1.6 |
| 6 | 1/6 | 13 | 10 | 3 | 0.9 |
| | | 60 | | | 5.6 |

Since $5.6 < 9.236$ the decision is not to reject H_0 .

The data do not provide sufficient evidence, at the 10% level of significance, to conclude that the die is loaded.

Example 1

Distribution of various ethnic groups in the population of a particular state based on a decennial U.S. census. Five years later a random sample of 2,500 residents of the state was taken, and census was taken.

Test, at the 1% level of significance, whether there is sufficient evidence in the sample to conclude that the distribution of ethnic groups in this state five years after the census had changed from that in the census year.

Example 1

| Ethnicity | Assumed Distribution | Observed Frequency |
|-----------------|----------------------|--------------------|
| White | 0.743 | 1732 |
| Black | 0.216 | 538 |
| American-Indian | 0.012 | 32 |
| Hispanic | 0.012 | 42 |
| Asian | 0.008 | 133 |
| Others | 0.009 | 23 |

Thank you
